## On Entoniscus mænadis. By M. A. Giard.

Almost at the moment when I made known the existence on the French coasts of the Entoniscus parasitic upon Pachygrapsus marmorutus, Fab.*, P. Fraisse met with this curious Isopod in the Bay of Naples, that is to say in the locality where it was discovered in 1787 by Cavolini. Fraisse further stated $\dagger$ that he had found the same parasite in Carcinus manas, but he did not establish the correctness of this determination by the comparative examination of the embryos, which furnish the best speeific characters in creatures which are so profoundly modified in tho adult state. As I had observed at various points on the shores of the Channel embryos of Entoniscus which had strayed into the incubatory cavity of Succulince Carcini, I repeatedly sought for Entoniscus in Carcinus muenas, but always without suceess, notwithstanding tho great number of crabs which were sacrificed for this purpose.

I have been more fortunate this spring, and the first crab which I opened at Wimereux furnished me with a fine Entoniscus, the ovigerons lamellæ of which contained perfectly mature embryos. The infested Curcinus mernus was a female of middle size, bearing a Succulinu the incubatory cavity of which was empty. The Entoniscus was placed on the left side of the crab, in the midst of the hepatic cæea of its host.

This Entoniscus, which I shall call Entoniscus menartis, is very distinct from Entoniscus Cavolinii. The liquid which circulates in the vessels contrasts by its red colour with the orange-yellow ground of the ovarian mass. The ovigerous sac, or, to be more exact, the mass of embryos ready for exclusion, presents a mauve-grey coloration, very different from the leaden tint of Entoniscus Cavolinii loaded with ova in the same stage of development. The embryo, especially, presents easily recognizable differential characters. We find no trace of the remarkable Nauplian eye, the existence of which I have indicated in the parasite of the Grapsus. The crystallines of the lateral eyes are more appreximated, and from these eyes there start, on each side of the head, ares of a reddish-brown pigment which meet upon the median part of the forehead. The sixth pair of thoracie legs presents nearly the same conformation as tho corresponding pair in the embryo of $E$. Cavolinii; nevertheless the terminal rod is shorter, and does not support a tuft of hairs as in the latter. From this point of view E. Cavolinii and E. menadis differ greatly from E. Salvatoris, Kossmann, in which the six pairs of thoracic feet are all similar $\ddagger$.

Kossmann has placed beyond doubt the existence of the male in the European Entonisci§. Further, he has supposed that in the

$\ddagger$ I resume, for the parasite of Portunus arcuatus, the name originally given by Kossmann, because this parasite appears to me to be specifically distiuct from that of Portunus puber, E. Moniezii, with which Kossmann would identify it.
§ See Kossmann's paper translated in the Ann. \& Mag. Nat. Hist. ser. 5, vol. x. p. 81.
species of the allied genus Cryptoniscus there is hermaphrodism with successive functioning of the two sexes and protandry. This hypothesis, strongly supported by the investigations of Bullar and Paul Mayer upon the Cymothoadina, appears to me to be very aeceptable in the present state of our knowledge, and I willingly extend it to the genera Hemioniscus and Entoniscus, and even to other less abnormal Bopyrina, such as Ione thoracict, which is also found at Wimereux in the branchial cavity of Callirnassa subterranea. We should thus easily explain how, in the case of animals so rare as the Entonisci, Fraisse and myself were able to find, comparatively often, upon the same cral, two or even three female individuals in different stages of development and unaccompanied by any male *.

The young imperfectly developed females would in this case be males, which, after having functioned as such, had succeeded in attaching themselves directly upon the erab, and continued their evolution as females, thanks to the more perfect nutrition which they would obtain in their new position. The great dimensions of the sac oceupied by the Entoniscus leaves, after the escape of the embryos, a free space much greater than in the case of the true Bopyri, and facilitates this change of place of the male, the activity of which is sufficient.

Sactulina Carcini is not very common at Wimereux ; the Entoniscus is very rare there. The coincidence of these two parasites upon the same crab therefore possesses a real interest, especially if we connect this observation with those made by Fritz Miiller upon E. Porcellance, and by Fraisse upon E. Carolinii. It is, it seems to me, a fresh example of what I have called the mutual assistance or the successive association of parasites in a determinate order, each species preparing the soil for those which are to follow it. Demonstrated first among the inscets, this law scems to me to be of rery general application, and it will doubtless furnish valuable indications in comparative pathology when it is applied to parasites of a lower grade, animal or vegetable.-Comptes Rentus, May 3, 1886, p. 1034 .

## On the Calcureous Sponges of Minora. By M. Lafscheivitz.

M. Lakschewitz has communicated to the Dorpat Society of Naturalists a preliminary note on the calcareous sponges of Minorca, founded upon collections made in 1882 by Prof. MI. Braun, chiefly in the harbour of Mahon and the Alcanfia inlet. He adopts Häckel's classification.

## Order CALCISPONGIÆ. <br> Fam. 1. Ascones. <br> 1. Ascetta 1 mimordialis, Häck.

Most of the specimens are flat cushion-like stocks of $10-40$ millim.

* Fraisse found the Entonisci upon seven females of Carcimus meenus without ova; one of these crabs bore two and the other three parasites. Upon a single Portumus. phber. I found two unequally developed specimens of Entoniscus Monienï, the only individuals of this species that I have been able to observe.
